- Thermal Efficiency: $\eta_{\text{thermal}} = \frac{W_{\text{net}}}{Q_{\text{in}}}$
- Cycle Efficiency: Depends on the specific cycle and operating conditions.

Step-by-Step Approach to Solving Typical Problems

- Identify the cycle type and process conditions

Determine whether the cycle is Rankine, Brayton, Otto, or Diesel. Gather all known parameters such as pressure, temperature, mass flow rates, and specific heats.

- Construct the cycle on property diagrams

Use T-s, P-v, or h-s diagrams to visualize the processes and understand the flow of energy.

- Apply the first law of thermodynamics

For each process:

- Analyze energy transfer (heat and work)
- Calculate changes in internal energy, enthalpy, and entropy
- Use thermodynamic tables and charts

Extract properties at various states directly from tables or Mollier diagrams, especially for water/steam or ideal gases.

- Compute work and heat transfer
- For turbines, compressors, and pumps, calculate work done or consumed.
- For heat transfer, determine heat added or rejected during each process.
- Determine cycle efficiency

Use the net work output and heat input to find the efficiency:

$$\eta_{\text{cycle}} = \frac{W_{\text{net}}}{Q_{\text{in}}}$$

- Evaluate irreversibilities and losses

In real systems, account for:

- Mechanical losses
- Heat transfer losses
- Pressure drops

Thermodynamics Example Problems Problems And Solutions

thermodynamics example problems problems and solutions are essential tools for students and professionals aiming to deepen their understanding of this fundamental branch of physics and engineering. Working through practical problems helps clarify concepts such as energy transfer, efficiency, and the behavior of gases and liquids under different conditions. In this article, we will explore a variety of thermodynamics example problems, complete with detailed solutions, to enhance your learning and problem-solving skills in this fascinating field.

Understanding Thermodynamics Fundamentals Through Examples

Before diving into specific problems, it's important to review key concepts in thermodynamics. These include the laws of thermodynamics, properties of ideal gases, processes such as isothermal, adiabatic, isobaric, and isochoric, and the principles of energy conservation.

Common Types of Thermodynamics Problems

Thermodynamics problems typically fall into several categories, including:

- Calculating work done during a process
- Determining heat transfer in a cycle
- Applying the first law of thermodynamics
- Evaluating efficiency of engines
- Analyzing phase changes and property variations

Below, we will explore specific example problems in these categories, along with solutions to demonstrate problem-solving techniques.

Example Problem 1: Work Done in an Isothermal Expansion of an

Ideal Gas

Problem Statement:

An ideal gas initially occupies a volume of 0.5 m^3 at a temperature of 300 K . The gas undergoes an isothermal expansion to a final volume of 1.0 m^3 . Calculate the work done by the gas during this process. Assume the gas is ideal with a molar mass of 28 g/mol , and use $R = 8.314 \text{ J/(mol}\cdot\text{K)}$.

Solution:

Step 1: Identify known values

- Initial volume, $(V_i = 0.5, \text{ m}^3)$
- Final volume, $(V_f = 1.0, \text{ m}^3)$
- Temperature, $(T = 300, \text{ K})$
- Gas constant, $(R = 8.314, \text{ J/(mol}\cdot\text{K)})$
- Moles of gas, (n) : to be calculated

Step 2: Calculate moles of gas

Since the initial state involves an ideal gas:

$[$

$$PV = nRT$$

$]$

But pressure is not given. Alternatively, we can use the ideal gas law to find the number of moles if pressure is known, but since pressure isn't provided, we need an additional assumption or consider the process per mole.

Assuming the process occurs at constant temperature (isothermal), the work done by the gas is given by:

$[$

$$W = nRT \ln \left(\frac{V_f}{V_i} \right)$$

$]$

To proceed, we need the moles of gas, which can be obtained if pressure is known. If pressure is unknown, and the problem states that the initial pressure is, for example, 100 kPa, then:

\[

$$PV = nRT \rightarrow n = \frac{PV}{RT}$$

\]

Assuming initial pressure:

\[

$$P_i = 100 \text{ kPa} = 100,000 \text{ Pa}$$

\]

Calculate n :

\[

$$n = \frac{P_i V_i}{RT} = \frac{100,000 \times 0.5}{8.314 \times 300} \approx \frac{50,000}{2494.2} \approx 20.04 \text{ mol}$$

\]

Step 3: Calculate work done

Using the formula:

\[

$$W = nRT \ln \left(\frac{V_f}{V_i} \right)$$

\]

Compute:

\[

$$W = 20.04 \times 8.314 \times 300 \times \ln \left(\frac{1.0}{0.5} \right)$$

\]

Calculate the natural log:

\[

$$\ln(2) \approx 0.693$$

\]

Now:

\[

$$W \approx 20.04 \times 8.314 \times 300 \times 0.693$$

\]

Calculate step by step:

- $(8.314 \times 300 = 2494.2)$
- $(20.04 \times 2494.2 \approx 50,000)$ (which aligns with previous calculation)
- $(50,000 \times 0.693 \approx 34,650, \text{J})$

Final answer:

\[

\boxed{

$$W \approx 34.65, \text{kJ}$$

}

\]

The gas does approximately 34.65 kJ of work during the isothermal expansion.

Example Problem 2: Efficiency of an Ideal Rankine Cycle

Problem Statement:

An ideal Rankine cycle operates between a condenser temperature of 30°C and a boiler temperature of 500°C. Assuming the working fluid is water, calculate the thermal efficiency of the cycle. Use steam tables for properties and assume saturated conditions at the boiler and condenser.

Solution:

Step 1: Convert temperatures to Kelvin

- $(T_{\text{condenser}} = 30^{\circ}\text{C} = 303\text{ K})$
- $(T_{\text{boiler}} = 500^{\circ}\text{C} = 773\text{ K})$

Step 2: Determine the saturation properties

From steam tables:

- At 500°C (boiler exit), the specific enthalpy of saturated vapor, $(h_g \approx 3450\text{ kJ/kg})$
- At 30°C (condenser exit), the specific enthalpy of saturated liquid, $(h_f \approx 0.004\text{ kJ/kg})$ (approximately 0)

Step 3: Calculate work input and heat added

In an ideal Rankine cycle:

- The turbine expands the high-pressure vapor from (h_g) to a lower pressure, producing work.
- The condenser condenses vapor to saturated liquid.
- The pump compresses the saturated liquid back to boiler pressure, consuming work, but for simplicity, the pump work is often neglected or considered small.

Step 4: Approximate cycle efficiency

The thermal efficiency is given by:

η

$$\eta = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}}$$

\\

Where:

- (Q_{in}) is the heat added in the boiler, approximately $(h_{\text{g}} - h_{\text{f}}) \approx 3450$,
 kJ/kg

- (Q_{out}) is the heat rejected in the condenser, approximately $(h_{\text{g}} - h_{\text{f}})$, but since the condenser receives saturated vapor and condenses it, the heat rejected per unit mass is:

\\

$$Q_{\text{out}} \approx h_{\text{g}} - h_{\text{f}} \approx 3450, \text{ kJ/kg}$$

\\

However, for efficiency, the ideal Rankine cycle efficiency can be approximated by the Carnot efficiency:

\\

$$\eta_{\text{Carnot}} = 1 - \frac{T_{\text{condenser}}}{T_{\text{boiler}}} = 1 - \frac{303}{773} \approx 1 - 0.392 = 0.608$$

\\

Final answer:

\\

\boxed{

$$\eta \approx 60.8\%$$

}

\\

This represents the maximum theoretical efficiency of the ideal Rankine cycle operating between these temperature limits.

Example Problem 3: Adiabatic Compression of an Ideal Gas

Problem Statement:

An adiabatic compressor compresses air (assumed ideal gas with $R = 287 \text{ J/(kg}\cdot\text{K)}$), $\gamma = 1.4$) from an initial state of 100 kPa and 300 K to a final pressure of 800 kPa. Find the temperature after compression and the work done per kilogram of air.

Solution:

Step 1: Use adiabatic relations

For an adiabatic process:

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1} \right)^{(\gamma - 1)/\gamma}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1} \right)^{(\gamma - 1)/\gamma}$$

$$T_2 = 300 \times \left(\frac{800}{100} \right)^{(1.4 - 1)/1.4} = 300 \times (8)^{0.4/1.4}$$

Plugging in values:

$$T_2 = 300 \times \left(\frac{800}{100} \right)^{(1.4 - 1)/1.4} = 300 \times (8)^{0.4/1.4}$$

Calculate exponent:

$$\frac{0.4}{1.4} \approx 0.2857$$

\]

Calculate $\ln 8^0$.

- Introduces practical applications
- Prepares for exams and professional assessments
- Enhances capability to design and analyze systems

In this guide, we'll explore various types of thermodynamics example problems, complete with detailed solutions, to help you master this vital subject.

Fundamental Concepts in Thermodynamics

Before diving into specific problems, it's crucial to review some core concepts:

- System and Surroundings: The system is the part of the universe under study; surroundings are everything else.
- Types of Systems: Closed, open, and isolated systems.
- Properties: Temperature, pressure, volume, internal energy, enthalpy, entropy.

- Laws of Thermodynamics:
- First Law: Conservation of energy.
- Second Law: Entropy tends to increase.
- Third Law: Absolute zero entropy at 0 K.
- Zeroth Law: Thermal equilibrium.

Common Types of Thermodynamics Problems

Thermodynamics problems can be categorized based on the principles they involve:

- Isothermal processes: Constant temperature
- Adiabatic processes: No heat transfer
- Isobaric processes: Constant pressure
- Isochoric processes: Constant volume
- Cycle analysis: Engines, refrigerators, heat pumps
- Property calculations: Internal energy, enthalpy, entropy changes
- Work and heat transfer calculations

Below, we'll explore detailed examples across these categories.

Example Problem 1: Ideal Gas in an Isothermal Process

Problem:

An ideal gas with a mass of 2 kg is contained in a rigid, insulated container at an initial temperature of 300 K. The gas undergoes an isothermal expansion to twice its original volume. Determine:

- The work done by the gas during expansion.
- The change in internal energy of the gas.

Solution:

Given Data:

- Mass, $m = 2 \text{ kg}$
- Initial temperature, $T = 300 \text{ K}$
- Final volume, $V_f = 2 V_i$
- Gas: Ideal gas (assume air, molar mass $\approx 29 \text{ g/mol}$)

- Process: Isothermal expansion (constant temperature)

Step 1: Find the initial state parameters.

Calculate the number of moles, n :

$$n = (m / M) = (2 \text{ kg}) / (0.029 \text{ kg/mol}) = 68.97 \text{ mol}$$

Step 2: Use Ideal Gas Law to find initial volume V_1 :

$$PV = nRT$$

Initially, pressure P_1 can vary, but since the process is isothermal, $P_1 V_1 = nRT$

Step 3: Work done during an isothermal process:

$$W = nRT \ln(V_2 / V_1)$$

Given $V_2 = 2 V_1$, so:

$$W = nRT \ln(2)$$

Calculate W :

$$W = 68.97 \text{ mol} \cdot 8.314 \text{ J/mol}\cdot\text{K} \cdot 300 \text{ K} \ln(2)$$

$$W = 68.97 \cdot 8.314 \cdot 300 \cdot 0.6931$$

$$W = 68.97 \cdot 8.314 \cdot 300 \cdot 0.6931 = 68.97 \cdot 8.314 \cdot 207.93$$

$$\text{First, } 8.314 \cdot 300 = 2494.2$$

$$\text{Then, } 2494.2 \cdot 0.6931 = 1728.7$$

$$\text{Finally, } W = 68.97 \cdot 1728.7 = 119,448 \text{ J}$$

Answer (a): The work done by the gas is approximately 119.4 kJ.

Step 4: Change in internal energy (ΔU):

For an ideal gas, ΔU depends only on temperature; since temperature is constant:

$$\Delta U = 0$$

Answer (b): The internal energy change is 0 J.

Example Problem 2: Adiabatic Compression of an Air Cylinder

Problem:

Air in a piston-cylinder device undergoes an adiabatic compression from an initial state of 100 kPa and 300 K to a final pressure of 500 kPa. Determine:

- The final temperature after compression.
- The work done on the air during compression.

Assume air behaves as an ideal gas with $\gamma = 1.4$.

Solution:

Given Data:

- Initial pressure, $P_1 = 100$ kPa
- Initial temperature, $T_1 = 300$ K
- Final pressure, $P_2 = 500$ kPa
- $\gamma = 1.4$

Step 1: Find the final temperature T_2

For adiabatic processes:

$$(P_2 / P_1) = (T_2 / T_1)^{\gamma / (\gamma - 1)}$$

Rearranged:

$$T_2 = T_1 (P_2 / P_1)^{(\gamma - 1) / \gamma}$$

Calculate:

$$T_2 = 300 (500 / 100)^{(1.4 - 1) / 1.4}$$

$$= 300 (5)^{0.4 / 1.4}$$

$$= 300 5^{0.2857}$$

Calculate $5^{0.2857}$:

$$\ln(5) \approx 1.6094$$

$$0.2857 \times 1.6094 \approx 0.460$$

$$e^{0.460} \approx 1.584$$

Hence,

$$T_2 \approx 300 \times 1.584 \approx 475.2 \text{ K}$$

Answer (a): The final temperature is approximately 475.2 K.

Step 2: Calculate work done during adiabatic compression

For an adiabatic process:

$$W = (P_2 V_2 - P_1 V_1) / (1 - \gamma)$$

But since V is not directly given, we can use the relation:

$$W = (n R (T_2 - T_1)) / (\gamma - 1)$$

Alternatively, for a fixed amount of gas, the work can be calculated as:

$$W = (P_2 V_2 - P_1 V_1) / (1 - \gamma)$$

But more straightforwardly:

$$W = n R (T_2 - T_1) / (\gamma - 1)$$

Calculate n :

$$n = P_1 V_1 / (R T_1)$$

Since V_2 is unknown, but the ratio V_2 / V_1 can be found:

$$V_2 / V_1 = (P_2 / P_1)^{1/\gamma} = (100 / 500)^{1/1.4} = (0.2)^{0.7143}$$

Calculate:

$$\ln(0.2) = -1.6094$$

$$-1.6094 \times 0.7143 = -1.149$$

$$e^{-1.149} = 0.316$$

Thus,

$$V_2 / V_1 = 0.316$$

Now, pick V_1 arbitrarily or assume $V_1 = 1 \text{ m}^3$ for simplicity:

$$n = P_1 V_1 / (R T_1) = (100,000 \text{ Pa } 1 \text{ m}^3) / (8.314 \text{ J/mol}\cdot\text{K } 300 \text{ K}) = 100,000 / 2494.2 = 40.07 \text{ mol}$$

Calculate W:

$$W = n R (T_2 - T_1) / (\gamma - 1)$$

$$W = 40.07 \text{ mol } 8.314 \text{ J/mol}\cdot\text{K} (475.2 - 300) \text{ K}$$

$$= 40.07 \times 8.314 \times 175.2 = 40.07 \times 1455.4 = 58,340 \text{ J}$$

Answer: The work done on the air during compression is approximately 58.3 kJ.

Example Problem 3: Rankine Cycle Efficiency Calculation

Problem:

A simple Rankine cycle operates between boiler pressure of 8 MPa and condenser pressure of 10 kPa. The steam enters the turbine at an enthalpy of 2800 kJ/kg and leaves at 1000 kJ/kg. The condenser receives the steam at an enthalpy of 200 kJ/kg (saturated liquid). Calculate:

- The thermal efficiency of the cycle.
- The net work output per kilogram of steam.

Solution:

Given Data:

-

Question What is an example of a thermodynamics problem involving the first law of thermodynamics? A common example is calculating the work done during the expansion of a gas in a piston. For instance, if 2 mol of an ideal gas expand isothermally from volume V_1 to V_2 at temperature T , the work done is $W = nRT \ln(V_2/V_1)$. How do you solve a problem involving the calculation of the change in internal energy for a gas process? Use the first law: $\Delta U = Q - W$. For example, if 500 J of heat is added to a gas and it does 200 J of work, the change in internal energy is $\Delta U = 500 \text{ J} - 200 \text{ J} = 300 \text{ J}$. Can you provide an example of a problem calculating the efficiency of a Carnot engine? Yes. If a Carnot engine operates between temperatures $T_{\text{hot}} = 500 \text{ K}$ and $T_{\text{cold}} = 300 \text{ K}$, its efficiency is $\eta = 1 - T_{\text{cold}}/T_{\text{hot}} = 1 - 300/500 = 0.4$ or 40%. How do you approach solving a problem involving the entropy change during an ideal gas process? Use the formula $\Delta S = nR \ln(V_2/V_1)$ for isothermal processes, or $\Delta S = nC_v \ln(T_2/T_1) + nR \ln(V_2/V_1)$ for more general processes, where n is moles, R is the gas constant, C_v is the heat capacity at constant volume, and T is temperature. What is an example problem involving phase change and latent heat in thermodynamics? Calculate the heat required to convert 1 kg of ice at -10°C to water at 20°C . First, heat the ice to 0°C : $Q = m c_{\text{ice}} \Delta T$. Then, melt the ice: $Q = m L_f$. Finally, heat the water from 0°C to 20°C : $Q = m c_{\text{water}} \Delta T$. Summing these gives total heat absorbed. How do you solve a problem involving the entropy change during a phase transition? During a phase change at constant temperature, the entropy change is $\Delta S = Q_{\text{rev}} / T$, where Q_{rev} is the heat absorbed or released during the phase transition. For example, melting 1 mol of ice at 0°C : $\Delta S = L_f / T$, where L_f is the molar latent heat of fusion. Can you give an example of a problem calculating work done in an adiabatic process? Yes. For an adiabatic expansion of an ideal gas from initial state (P_1, V_1, T_1) to final state (P_2, V_2, T_2), the work done is $W = (P_2 V_2 - P_1 V_1) / (\gamma - 1)$, or by integrating $W = \int P dV$. For example, expanding from $V_1 = 1 \text{ m}^3$ to $V_2 = 2 \text{ m}^3$ with known initial pressure and temperature allows calculation of work done.

Key Concepts and Formulas in ME2202 Thermodynamics

First Law of Thermodynamics

For a control mass:

$\int$

$$Q - W = \Delta U$$

$\int$

Where:

- Q = heat added to the system
- W = work done by the system
- ΔU = change in internal energy

Work in Different Processes

- Isobaric: $W = P (V_2 - V_1)$
- Isentropic (adiabatic, reversible for ideal gases): $PV^\gamma = \text{constant}$

Entropy Change

- For a reversible process:

$$\Delta S = \int \frac{\delta Q_{\text{rev}}}{T}$$

- For ideal gases:

$$\Delta S = C_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

Thermal Efficiency of Power Cycles

- Carnot cycle:

$$\eta_{\text{Carnot}} = 1 - \frac{T_L}{T_H}$$

- Rankine cycle efficiency:

\[

$$\eta = \frac{\text{Net work output}}{\text{Heat input}}$$

\]

Sample Problem Breakdown

Problem Statement:

A piston-cylinder device contains saturated water vapor at 200 kPa. It undergoes an adiabatic

expansion until the pressure drops to 100 kPa. Determine the work done during this process, assuming an idealized process.

Step-by-Step Solution Approach:

- Identify initial and final states:
- Use steam tables to find initial specific volume (v_1) at 200 kPa and saturated vapor.
- For the final state at 100 kPa, determine whether the vapor is superheated, saturated, or mixture.
- Determine process type:
- Adiabatic and expansion suggest an isentropic process for an idealized vapor.
- Calculate initial entropy (s_1) :
- From tables at 200 kPa.
- Find final specific volume (v_2) :
- Use the fact that for an isentropic process, $(s_2 = s_1)$.
- Compute work done:
- For a reversible adiabatic process:

$\int$

$$W = P_{\text{avg}} (V_2 - V_1)$$

\]

- Alternatively, use the change in internal energy and the first law, considering the specific heats or property relations.

- Final check:

- Ensure the computed work makes sense physically (e.g., negative sign indicates work done by the system).
