Question What are the key differences between mathematical statistics and probability theory? Mathematical statistics focuses on developing methods for collecting, analyzing, and interpreting data, often involving estimation and hypothesis testing. Probability theory, on the other hand, studies the mathematical foundations of randomness and uncertainty, providing models to quantify likelihoods of events. While probability theory provides the theoretical basis, mathematical statistics applies these concepts to real-world data. **Answer** How can I approach solving a problem in mathematical statistics using a Bayesian framework? To solve a problem using Bayesian methods, start by defining a prior distribution that reflects your initial beliefs about the parameters. Then, gather data and compute the likelihood function. Using Bayes' theorem, update the prior with the likelihood to obtain the posterior distribution. Finally, analyze the posterior to make inferences or predictions about the parameters. What are common challenges faced when implementing Bayesian solutions in statistical problems? Common challenges include selecting appropriate prior distributions, especially when prior information is limited; computational complexity involved in calculating posterior distributions, especially for complex models; and ensuring convergence and mixing in Markov Chain Monte Carlo (MCMC) methods. Additionally, interpreting Bayesian results in a frequentist context can sometimes be challenging. Can you recommend resources or tools for learning Bayesian methods in mathematical statistics? Yes, popular resources include 'Bayesian Data Analysis' by Gelman et al., and online courses like Coursera's 'Bayesian Statistics' by the University of California. Software tools such as R (with packages like 'rstan' or 'brms') and Python (with libraries like PyMC3 or PyMC) are also invaluable for implementing Bayesian models and solutions. How does the solution approach differ when using classical versus Bayesian methods in statistics? Classical (frequentist) methods rely on long-run frequency properties and often focus on point estimates, confidence intervals, and hypothesis testing without incorporating prior beliefs. Bayesian methods, however, incorporate prior information through probability distributions and produce a full posterior distribution for parameters, allowing for more flexible and probabilistic inferences. The choice depends on the problem context, available prior knowledge, and the desired interpretation of results.

Solution:

- The sample mean $\bar{x}$ is an unbiased estimator of μ .
- Since the variance is known, the confidence interval is:

Solution:

- Null hypothesis: $H_0: p = 0.6$
- Alternative hypothesis: $H_1: p \neq 0.6$
- Test statistic:

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1 - p_0)}{n}}}$$

where $\hat{p} = 65/100 = 0.65$.

- Compute:

$\backslash$

$$z = \frac{0.65 - 0.6}{\sqrt{\frac{0.6 \times 0.4}{100}}} = \frac{0.05}{\sqrt{0.0024}} \approx 1.02$$

 $\backslash$
