Question 1: Histopathological Features

"A liver biopsy shows periportal inflammation, interface hepatitis, and piecemeal necrosis. Which condition is most consistent with these findings?"

Options:

- A) Autoimmune hepatitis
- B) Alcoholic liver disease
- C) Non-alcoholic fatty liver disease
- D) Cirrhosis

Correct Answer: A) Autoimmune hepatitis

Explanation:

The histopathological features described—periportal inflammation, interface hepatitis, and piecemeal necrosis—are characteristic of autoimmune hepatitis. These features reflect immune-mediated destruction at the portal-parenchymal interface. Conversely, alcoholic liver disease often shows steatosis, ballooning, and Mallory bodies, while NAFLD primarily exhibits macrovesicular fat accumulation without prominent interface hepatitis.

Question 2: Disease Pathogenesis

"Which of the following is the primary mechanism leading to hepatocellular carcinoma in chronic hepatitis B infection?"

Options:

- A) Integration of viral DNA into host genome
- B) Chronic inflammation leading to fibrosis
- C) Accumulation of fatty acids within hepatocytes
- D) Autoimmune destruction of hepatocytes

Correct Answer: A) Integration of viral DNA into host genome

Explanation:

Hepatitis B virus can integrate its DNA into the host genome, leading to genetic instability and oncogenic mutations, which directly contribute to hepatocarcinogenesis. While chronic inflammation and fibrosis are risk factors, the direct integration event is a key pathogenic mechanism. Fat accumulation relates more to fatty liver disease, and autoimmune destruction is characteristic of autoimmune hepatitis.

Limitations and Challenges of MCQ Use in Liver Pathology

Despite their utility, MCQs—including those from Liver Pathology MCQs Dr. Mys—have inherent limitations:

- Risk of rote memorization rather than conceptual understanding
- Potential for ambiguous or poorly worded questions
- Variability in difficulty levels
